Abstract

The invention includes the fitted quaternary structure of insulin receptor. It also includes methods of identifying compounds that modulate insulin receptor activity by producing a compound that interacts with all or part of the fitted quaternary structure of
5 insulin receptor or a fragment or derivative thereof and which thereby modulates insulin receptor activity.

Identification of Compounds for Modulating Dimeric Receptors

Field of the Invention

The invention relates to methods of using the three dimensional structure of an intrinsically covalent dimeric receptor, preferably the insulin receptor, to identify test compounds that will interact with the dimeric receptor and modulate its activity. The invention also includes compounds identified using the methods of the invention.

Background of the Invention

Covalent dimeric receptors are found on almost all cells in mammals. These receptors include IR (insulin receptor), IGF-I R (insulin-like growth factor I) and IRR (the insulin receptor-related receptor). In the case of IR, insulin binding to IR is essential for its manifold effects such as glucose homeostasis, increased protein synthesis, growth, and development in mammals. IR belongs to the superfamily of transmembrane receptor TKs that include the monomeric epidermal growth factor receptor (EGFR) and platelet-derived growth factor receptor (PDGFR). In contrast, IR and its homologues IGF-I R and IRR are sub-types of this family that are intrinsic disulfide-linked dimers of two heterodimers of the form $(\alpha\beta)_2$ (1,2). Monomeric receptor TKs are inactive, but are activated by ligand-induced dimerization that results in autophosphorylation. Dimeric IR-like TKs are also inactive, and are activated by ligand binding without further dimerization. Insulin binding to the extracellular domain of IR results in autophosphorylation of specific tyrosines in the cytoplasmic domain to initiate an intracellular signal transduction cascade (3). However, the structural basis for the mechanism of IR activation by extracellular insulin binding has not been elucidated because the quaternary structure of IR was unknown. Only some of the smaller domains have yielded high resolution structural information.

Diabetes may be caused by mutant IR (eg. acanthosis nigrican or leprechaunism. Insulin resistance leading to diabetes or similar symptoms may also occur.). Diseases are also caused by insufficient amounts of IR ligand. For example, in diabetes, the pancreas produces insufficient amounts of insulin. Insulin activates IR and allows cells to absorb and store glucose. In the absence of adequate insulin, glucose accumulates in excessive amounts in the blood (hyperglycemia). The symptoms of diabetes may include poor

blood circulation, blindness and organ damage. These symptoms often lead to premature death.

Diabetes is presently treated by insulin replacement therapy. This treatment has been very successful, but it still has problems such as glycemic control. Poor glycemic control can cause retinopathy, poor blood circulation and the other problems associated with diabetes. It is also difficult to formulate insulin for slow release. Modified insulins have been created in an attempt to address problems with insulin therapy. In some cases, "super-insulins" have been created to increase the activation of insulin receptor by its ligand. In other cases, binding to insulin receptor is not substantially increased, but the ligand has more favourable formulation properties. For example, in Humalog™, a lysine and a proline in insulin are switched to provide more favourable solubility characteristics.

These drug design strategies have been based on limited information, such as the chemical properties of the insulin molecule. In some cases, insulin has been randomly modified and then assayed to determine the effects on insulin activity. While there has been success in producing insulin variants, both of these approaches are time consuming because variants are made without a clear understanding of the effect of the variation on binding to insulin receptor. There is a need to obtain additional information about the insulin receptor in order to provide a rational basis for drug design.

For example, it would be helpful if the quaternary structure, including the ligand binding site, of IR was available and characterized to the detail of amino acids. However, it is very difficult to obtain information about the quaternary structure of dimeric receptors. For example, large transmembrane proteins such as cell surface hormone receptors have been difficult to crystallize as intact molecules for high-resolution structural study. They are also too large for NMR spectroscopy. The 480-kDa insulin receptor (IR) has thus not been crystallized as an intact molecule, and its quaternary structure remains unknown to date.

Summary of the Invention

We have obtained the quaternary structure of IR. We used low-dose low-temperature dark field scanning transmission electron microscopy (STEM). Using

electron micrographs of the insulin-IR complex we have reconstructed the three-dimensional quaternary structure of the intact receptor complexed with gold-labeled insulin ligand. Although IR has been purified and studied for over 15 years, this is the first 3D reconstruction of its entire dimeric structure. Contiguous high densities within the 3D structure indicate a two-fold symmetry for this dimeric membrane receptor, as well as a logical sequence for its biochemical subdomains from the observed binding of a single insulin on the ectodomain to the juxtaposition of the pair of intrinsic tyrosine kinases (TKs) of the intracellular domain.

We determined structural relationships of the IR subdomains in the 3D reconstruction of IR and a structural basis for IR activation by insulin. In the absence of ATP which is required to complete the activation of the IR tyrosine kinase, the structure of this insulin-bound IR can be considered to be in a transitional state, with its kinase domains intermediate between the inactive and activated structures observed by x-ray crystallography (4).

The quaternary structure of IR, fitted with the atomic co-ordinates of highly analogous domains of IR has resulted in a detailed description of the insulin binding site on the insulin receptor. Moreover, the combination of structural detail from 20 Å to atomic resolution yielded a self-consistent model for the mechanism of the initial phase of insulin action on binding to effect intracellular receptor tyrosine kinase activation.

The complete IR model provides a simple mechanical paradigm for the reversible transmembrane signalling response. It explains the need for the complexity of structural components to control both inhibition and accommodation of tyrosine kinase activation. It gives ready structural explanations for many normal effects, for various mutations and for mild chemical reduction of the insulin receptor. It thus provides a comprehensive structural basis for the mechanics of transmembrane signal transduction for the intrinsically dimeric insulin-like membrane receptors.

The details of the insulin binding site provide an explanation of binding of normal human insulin as well as of the lesser or greater binding of insulin from other animals to the

human IR and explains the binding of modified insulins such as "super-insulins", Humalog™ and other insulin analogs.

One aspect of the invention includes a method of identifying a compound that modulates insulin receptor activity, including producing a compound that interacts with
5 all or part of the fitted quaternary structure of insulin receptor or a fragment or derivative thereof and which thereby modulates insulin receptor activity. In one embodiment, the method further includes synthesizing the compounds.

Another aspect of the invention includes a method of identifying a compound that modulates insulin receptor activity, including comparing the structure of a compound for
10 modulating insulin receptor activity to all or part of the fitted quaternary structure of insulin receptor or a fragment or derivative thereof to determine whether the compound is likely to modulate insulin receptor activity.

The method may further include determining whether the compound modulates the activity of the insulin receptor or a fragment or a derivative thereof having IR activity
15 in an *in vivo* or *in vitro* assay. The compound identified by the method is an IR agonist or an IR antagonist. In one variation, the fitted quaternary structure of IR comprises substantially the entire fitted quaternary structure of IR.

The method may further include:

- a) introducing into a computer program information defining a ligand binding site
20 conformation including at least one residue from monomer A in Table I and at least one residue from monomer B in Table I, the ligand binding site defined by the approximate amino acid distances listed in Table I, wherein the program displays the quaternary structure thereof;
- b) comparing the structural coordinates of the compound to the structural coordinates
25 of the ligand binding site and determining whether the compound fits spatially into the ligand binding site and is capable of changing IR from an inactive conformation to an active conformation or biasing IR toward an active conformation;

wherein the ability to change IR from an inactive conformation to an active conformation or bias IR toward an active conformation is predictive of the ability of the compound to agonize IR activity.

The method may further include preparing the compound that fits spatially into the ligand binding site and determining whether the compound agonizes IR activity in an IR activity assay. The invention also includes a method of identifying a compound which agonizes IR or a fragment or derivative thereof having IR activity, the IR, fragment or derivative including a ligand binding site with at least one of the residues and approximate structural coordinates of each of monomer A and monomer B listed in Table 1, the method including the steps of:

- a) providing the coordinates of the ligand binding site of the IR to a computerized modeling system;
- b) identifying compounds which interact with the ligand binding site and change IR from an inactive conformation to an active conformation or bias IR toward an active conformation.

The invention also includes a method of drug design including using at least one of the amino acids of each of monomer A and monomer B of IR in Table 1 to determine whether a compound interacts with the ligand binding site of IR or a fragment or derivative thereof having IR activity and is capable of changing IR from an inactive conformation to an active conformation or biasing IR toward an active conformation.

Another aspect of the invention includes a method of agonizing IR including administering to a mammal a compound that fits spatially into the ligand binding site of IR, the compound interacting with at least

a) one IR amino acid in monomer A listed in Table 1; and

b) one IR amino acid in monomer B listed in Table 1;

wherein the compound is capable of changing IR from an inactive conformation to an active conformation or biasing IR toward an active conformation.

The method may further include:

5 a) introducing into a computer program information defining a ligand binding site conformation including at least one residue from monomer A in Table I and at least one residue from monomer B in Table I, the ligand binding site defined by the approximate amino acid coordinates listed in Table I, wherein the program displays the quaternary structure thereof;

10 b) comparing the structural coordinates of the compound to the structural coordinates of the ligand binding site and determining whether the compound fits spatially into the ligand binding site and is capable of changing IR from an active conformation to an inactive conformation or biasing IR toward an inactive conformation;

15 wherein the ability to change IR from an active conformation to an inactive conformation or bias IR toward an active conformation is predictive of the ability of the compound to antagonize IR activity.

The method may include preparing the compound that fits spatially into the ligand binding site and determining whether the test compound antagonizes IR activity in an IR activity assay.

20 Another aspect of the invention includes a method of identifying a compound which antagonizes IR or a fragment or derivative thereof having IR activity, the IR, fragment or derivative including a ligand binding site with at least one of the residues and approximate distances of each of monomer A and monomer B listed in Table I, the method including the steps of:

25 a) providing the coordinates of the ligand binding site of the IR to a computerized modeling system;

- b) identifying compounds which interact with the ligand binding site and change IR from an active conformation to an inactive conformation or bias IR toward an inactive conformation.

A variation of the invention includes a method of drug design including using at least one of the structural coordinates from each of monomer A and monomer B of IR in Table 1 to determine whether a compound interacts with the ligand binding site of IR or a fragment or derivative thereof having IR activity and is capable of changing IR from an active conformation to an inactive conformation or biasing IR toward an active conformation.

- 10 The invention also includes a method of antagonizing IR by administering to a mammal a compound that fits spatially into the ligand binding site of IR, the compound interacting with at least:

a) one IR amino acid in monomer A listed in Table 1; and

b) one IR amino acid in monomer B listed in Table 1;

- 15 wherein the compound is capable of changing IR from an active conformation to an inactive conformation or biasing IR toward an active conformation. In a variation of the method, the ability of the compound to fit spatially into the ligand binding site is determined by comparing the structural coordinates of the compound with the structural coordinates of IR. The ability of the compound to change the conformation of IR can be
20 determined by comparing the structural coordinates of the compound with the structural coordinates of IR.

Another variation of the invention includes:

- a) introducing into a computer program information defining a cam including at least one residue from the Cam-loop segment in Table 2 and at least one residue from
25 the L1 surface in Table 2, wherein the program displays the structure thereof and its relation to other IR domains;

- b) comparing the structural coordinates of the compound to the structural coordinates of the cam and determining whether the compound interacts with the cam and is capable of changing IR from an inactive conformation to an active conformation or biasing IR toward an active conformation;

5 wherein the ability to change IR from an inactive conformation to an active conformation is predictive of the ability of the compound to agonize IR activity. The method can further include preparing the compound that interacts with the cam and determining whether the test compound agonizes IR activity in an IR activity assay. The invention includes a method of identifying a compound which agonizes IR or a fragment or
10 derivative thereof having IR activity, the IR, fragment or derivative including a cam with at least one of the residues and approximate structural coordinates of the cam-loop segment and the L1 surface listed in Table 2, the method including the steps of:

- a) providing the coordinates of the cam to a computerized modeling system;
- b) determining compounds which interact with the cam and change IR from an
15 inactive conformation to an active conformation or bias IR toward an active conformation.

The invention includes a method of drug design including using at least one of the structural coordinates from each of cam-loop segment and the L1 surface listed in Table 2 to determine whether a compound interacts with the cam of IR or a fragment or derivative
20 thereof having IR activity and is capable of changing IR from an inactive conformation to an active conformation or biasing IR toward an active conformation. A variation of the method of agonizing IR includes administering to a mammal a compound that fits spatially into the cam of IR, the compound interacting with at least one of the residues and approximate structural coordinates of the cam-loop segment and the L1 surface listed
25 in Table 2; wherein the compound is capable of changing IR from an inactive conformation to an active conformation or biasing IR toward an active conformation.

The method can further include:

a) introducing into a computer program information defining a cam conformation including at least one residue from the Cam-loop segment in Table 2 and at least one residue from the L1 surface in Table 2, wherein the program displays the structure thereof and its relation to other IR domains;

5 b) comparing the structural coordinates of the compound to the structural coordinates of the cam and determining whether the compound interacts with the cam and is capable of changing IR from an active conformation to an inactive conformation;

wherein the ability to change IR from an active conformation to an inactive conformation is predictive of the ability of the compound to antagonize IR activity. The method can
10 additionally include preparing the compound that interacts with the cam and determining whether the test compound antagonizes IR activity in an IR activity assay.

The invention also includes a method of identifying a compound which antagonizes IR or a fragment or derivative thereof having IR activity, the IR, fragment or derivative including a cam with at least one of the residues and approximate structural
15 coordinates of the cam-loop segment and the L1 surface listed in Table 2, the method including the steps of:

a) providing the coordinates of the cam to a computerized modeling system;

b) identifying compounds which interact with the cam and change IR from an active conformation to an inactive conformation or bias IR toward an active
20 conformation.

Another variation of the invention includes a method of producing an IR modulator including using at least one of the structural coordinates from each of cam-loop segment and the L1 surface listed in Table 2 to determine whether a compound interacts with the cam of IR or a fragment of IR or derivative thereof having IR activity and is capable of
25 changing IR from an active conformation to an inactive conformation or biasing IR toward an active conformation.

01192150 1999

The method of antagonizing IR can include administering to a mammal a compound that interacts with the cam of IR, the compound interacting with at least one of the residues and approximate structural coordinates of the cam-loop segment and the L1 surface listed in Table 2; wherein the compound is capable of changing IR from an active conformation to an inactive conformation or biasing IR toward an active conformation. 5 The ability of the compound to interact with the cam can be determined by comparing the structural coordinates of the compound with the structural coordinates of IR. In the method of the invention, wherein the ability of the compound to change the conformation of IR can be determined by comparing the structural coordinates of the compound with 10 the structural coordinates of IR.

The methods of the invention may use free IR or IR bound to insulin in an IR:insulin complex.

Another aspect of the invention includes a computer medium having recorded thereon data of an IR receptor, said data sufficient to model all or part of the quaternary 15 structure of the receptor. The data can comprise structural coordinates of an IR receptor, the coordinates sufficient to model all or part of the quaternary structure of the receptor. The quaternary structure of the receptor can include substantially all of the quaternary structure of the receptor.

The invention also includes an insulin analog or other analog or mimetic 20 identified by the methods of the invention.

The invention also includes a method of identifying agonists of IR by rational drug design including: producing an agonist for IR that will interact with amino acids in the IR ligand binding site or IR cam based upon the structure coordinates of the IR:insulin complex. The method of may further include synthesizing the agonist and 25 determining whether the agonist agonizes the activity of IR in an *in vivo* or an *in vitro* assay. In a method of the invention, the co-ordinates of the IR:insulin complex can be obtained from an IR: insulin complex prepared for EM. The co-ordinates of the IR:insulin complex may be obtained by means of computational analysis.

The agonist can be designed to interact with at least one amino acid in monomer A in Table 1 and at least one amino acid in monomer B in Table 1 and cause IR to change from an inactive conformation to an active conformation or bias IR toward an active conformation.

5 The method of identifying a compound that modulates insulin receptor and insulin interactions or activity, can include:

- a) designing a compound for modulating insulin receptor activity based upon the fitted quaternary structure of insulin receptor bound to insulin.

The method can further synthesizing the compound and determining whether the
10 compound modulates the interactions or activity of the insulin receptor and insulin.

Another aspect of the invention includes a method of identifying a compound that modulates insulin receptor and insulin interactions or activity, including:

- a) comparing a compound for modulating insulin receptor activity to the quaternary structure of insulin receptor bound to insulin to determine whether the compound
15 is likely to modulate insulin receptor and insulin interactions or activity;
- b) determining whether the potential compound modulates the interactions or activity of the insulin receptor and insulin.

The compound may agonize or antagonize insulin receptor and insulin interactions or activity. The method of identifying how a compound interacts with IR activity may include
20 comparing the compound to all or part of the fitted quaternary structures of IR.

Another aspect of the invention includes a computer readable medium including all or part of the fitted quaternary structure of IR as shown in a figure or described in the application.

Another aspect relates to an insulin analog identified by a method of the invention. The invention includes a method of agonizing insulin receptor including administering a
25 an effective amount of the analog. The invention also includes a method of medical treatment of diabetes or hyperglycemia including administering to a mammal having diabetes or hyperglycemia a pharmaceutical composition including an effective amount of the analog. Mimetics or other insulin variants may also be used.

Brief Description of the Drawings

Preferred embodiments are described in relation to the drawings, in which:

Figure 1. Receptor-binding assay of Nanogold-insulin. Receptor-binding activity of purified Nanogold-insulin was compared to that of bovine insulin in a receptor-binding assay using human insulin receptor as described (9). Inset shows the mass spectrum obtained from the MOLDI-TOF analysis of purified Nanogold-insulin (7).

Figure 2. STEM dark field images of human insulin receptor /Nanogold-insulin (HIR/NG-BI) complex. A) Raw images showing several complexes. Arrowheads point to intense signals from Nanogold marker. Scale bar = 20 nm. B) HIR/NG-BI images extracted from image fields, after low pass filtering to 1.0 nm and boundary determination (left column). High density threshold representation of extracted images showing one (top five images) or two (bottom two images) sites of Nanogold location (right column).

Figure 3. Three-dimensional reconstruction of the HIR/NG-BI complex from 704 STEM dark field images. A) Density threshold representing the total expected volume for the complex [1]; intermediate density threshold, unsymmetrized, showing higher contiguous densities [2]; high density threshold of [2] showing only the Nanogold label [3]. Circles in the panels indicate location of the gold marker within the reconstructions. The resolution was 20 Å as measured by Fourier phase residual analysis of two reconstructions with 352 images each (13). B) Reconstruction with two-fold symmetry at intermediate density thresholds in different orientations, indicating the relationship and connectivity of the structural domains. Labels, for only one $\alpha\beta$ monomer of the dimeric HIR, refer to biochemical domains. Arrowhead indicates the proposed plane of the cell membrane lipid bilayer. L1, C-R, L2 = L1-Cysteine-rich-L2 domains; CD = connecting domain; Fn1, Fn2 = fibronectin III repeats 1 and 2; TK = tyrosine kinase; TM = transmembrane domain.

Figure 4. Fitting of biochemical domains and their known x-ray structures to the 3D reconstruction. A) Schematic domain structure for one $\alpha\beta$ monomer, derived from i) connectivity of the 3D reconstruction at intermediate density threshold (Fig. 3), ii) from the primary domain sequence, iii) from the requirement for two disulfides on the two-fold symmetry axis between the two α subunits (4), iv) the fit of the known domain structures,

and v) the principle of keeping domains of unknown structure as compact as possible. Distances measured in the 3D reconstruction between locations of subdomains CD, Fn1 and the symmetrical disulfides were commensurate with numbers of intervening amino acid residues (structures not shown to scale; α subunit shown in red, β subunit in blue and green, unknown structures are spheres or lines): A = TK activation loop; 1 = Cys524; 2 = Cys682, 683, 685; 3 = alpha-beta disulfide between Cys647 and Cys872; arrowhead = proreceptor cleavage site; other labels as described in Fig. 3B. B) Representative fitting of L1-Cys-rich-L2 domains as approximate cylinders to ectodomain structure of 3D reconstruction (cf. Fig. 3B, side view, 0; for ribbon structure see Fig 7A). One insulin molecule (purple ribbon, PDB: 1BEN) inserted with its receptor-binding domain contacting the L1-Cys-rich domains of one subunit (fuchsia) and the L2 domain of the other (red). The Nanogold marker (yellow) on Phe1 of insulin B chain positioned to coincide with the high-density site of reconstruction. C) Right angle side view of (B) (cf. Fig. 3B, side view 90) with L1-Cys-rich-L2 domains (insulin partly hidden), fitted TK structure (green ribbon, PDB: 1IRK) and two dimeric FnIII structures (blue and red ribbons, PDB: 1mFn). Red ribbons represent the portion of Fn1 derived from subunit. Activation loop (black ribbon) of left TK domain is shown in its crystallographic position. A-loop (dark blue) of symmetry-related right TK domain extended to overlap peptide substrate position of opposite TK in peptide-bound state (4). See also (D). D) Right angle top view of (B) (cf. Fig. 3B, top view) showing the positions of the FnIII domains (top and bottom, blue/red) and the TK domains (green). Crystallographic position of activation loop (black) is uppermost within one TK domain, while extended activation loop (dark blue) of the other TK domain is below. One square in the wire mesh is 6.5 Å.

Figure 5

a Three-dimensional structure of the human insulin receptor reconstructed images of the purified dimeric insulin receptor complexed with insulin obtained via low dose scanning transmission cryomicroscopy [1]. Density threshold at 85% of total volume to show contiguity of structure. Maximum diameter is 150 Å. Various regions of one $\alpha\beta$ monomer of the dimeric structure labelled as determined from insulin location, connectivity, mass distribution and fitting of known subdomain structures. (i), View as seen from the exterior of the cell, down the two-fold symmetry axis of the $(\alpha\beta)_2$ heterodimer. Partially transparent gray disc represents cell membrane with fainter regions of structure on distal side of membrane. (ii), View at right angles to A with extracellular components above gray translucent symbolic cell membrane. (iii), View from interior of cell with fainter structures on distal (exterior) side of modelled membrane. Arrow head points to cam-like feature (see text). For domain abbreviations see Fig. 6.

b Simplified, stylized model of insulin-IR in the same orientations as Fig. 5a. (i), View from exterior of cell. (ii), Side view (cell membrane edge-on). (iii), View from interior of cell. Corresponding subdomains for one $\alpha\beta$ monomer (fuchsia) are indicated. The other $\alpha\beta$ monomer (blue) is symmetrically related. Stylized catalytic regions and activation loops (gold and black spheres and hairpins) are indicated on TK domains. The two α - α disulphide bonds (1,2, yellow) modelled on two-fold axis in strained configuration. Cams (arrow head, black and gold discs) in position permissive for transactivation. Insulin ligand represented as red disc. For domain abbreviations see Fig. 6.

c Stylized model of IR in the absence of insulin. Same orientations as Fig. 5b. (i), View from exterior of cell, with separated L1-Cys-rich domains. (ii), Side view (cell membrane edge-on). (iii), View from interior of cell, with separated TK domains. Activation loops (arrow) do not reach catalytic loops (spheres on TKs). Cams (arrow head, black and gold discs) in position to block mutual approach of Fn2/TM/TK assemblies. Pair

of Cys-Cys bonds (1, 2, yellow) in relaxed equilibrium positions. Insulin (red disc) in position to bind to one $\alpha\beta$ monomer. For domain abbreviations see Fig. 6.

Figure 6

Sequential spatial arrangement of the subdomains of one $\alpha\beta$ monomer of the insulin receptor deduced from the 3D structure [1]. The N-terminal of the α subunit (red) is at the top, the C-terminal of the β subunit (blue) near the bottom. The domains and their delimiting amino acid sequences [5] are: α N-terminal - 1 - L1 - 158/159 - cysteine-rich (CR) - 310/311 - L2 - 470/471 - connecting-domain/ α Fibronectin0 (CD/Fn0) - 572/573 - α Fibronectin1 (α Fn1) - 661/662 - α -insert-domain (ID) - 719 - α C-terminal; β N-terminal - 724 - β -ID - 779/780 - β Fn1 - 816/817 - β Fn2 - 913/914 - juxtamembrane - 929/930 - transmembrane (TM) - 952/953 - juxtamembrane - 977/978 - tyrosine-kinase (TK) - 1283/1284 - C-terminal region - 1388 - β C-terminal. Other important residues are Cys524 (denoted by "1"), which forms an α - α bond on the two-fold symmetry axis, as does one of Cys682, Cys683 or Cys685 (shown as "2"). An α - β bond is formed by Cys647 in Fn1 of the α subunit and Cys872 in Fn2 of the β subunit (shown as "3"). "x" marks the cleavage site between the α and β subunits in the pro-receptor. The catalytic loop and the activation loop (shown as "A-C"; residues 1130-37 and 1149-70, respectively) are approximately in the central region of the tyrosine kinase structure [10,11].

Figure 7

a Side view of IR dimer structure at volume corresponding to total receptor mass, in wire mesh representation rotated 90° with respect to 5a(ii), fitted centrally with two L1-CR-L2 regions of IR as adapted from the co-ordinates of the corresponding IGF-1R structure. Aminoacid backbone representation. One L1-CR-L2 monomer region is shown in red, the other in fuchsia. The diamond-shaped opening is the modelled insulin binding site with one Nanogold-insulin fitted into the site (see Fig. 8).

b End view of full-mass representation of IR dimer. Left half: surface rendering; right half: wire mesh representation. Fitted structure of two IR-adapted L1-CR-L2 regions (red and fuchsia). Arrow: cam-like region on CR domain.

c Higher density solid surface representation slightly rotated of view in Fig. 7b showing location of CR cam regions of atomic structure against Fn2 domains of 3D reconstruction.

Figure 8

a View in parallel stereo representation of IR insulin-binding region of docked L1-CR-L2 regions (red and fuchsia; cf. Fig. 7a) fitted with insulin (brown). Backbone representation except for aminoacid sidechains tabulated in Table 1. See text for details.

b Insulin contacts with one L1-CR-L2 monomer (fuchsia). Slight rotation from Fig. 8a. The gold sphere represents the Nanogold label on insulin used in the 3D reconstruction. See text.

c Insulin contacts with second L1-CR-L2 monomer (red).

Figure 9

Simplified schematic of structural changes during activation of insulin receptor. a. Inhibitory state. Ectodomain of dimeric α subunits each with two differing insulin binding sites and blocking cam. Unbound bivalent insulin. β subunits resting against cams, crossing membrane, with tyrosine kinase (TK) domains separated. Arrows indicate thermally induced motion. b, Insulin bound state. Blocking cams rotated, β subunits resting against centre of ectodomain. TK domains juxtaposed for transphosphorylation.

Figure 10

A. Views (parallel stereo) of fibronectin domains docked into ectodomain quaternary structure of IR. Fn0 and α ID regions are modelled as extending around L2 to the central 2-fold symmetry axis to form α - α disulphide bonds. The α - β disulphide is shown between α Fn1 and Fn2. The domains of one $\alpha\beta$ monomer only are coloured and labelled for identification. For clarity, LCL is shown only with part of the CR domain and all of the L2 domain (amino acids 250 to 470).

B. Complete fit of known IR and IR-like domains as docked into 3D EM reconstruction of quaternary structure of IR dimer. The TM and juxtamembrane domains, of unknown structure, have been modelled as helix

and loop structures and arbitrarily placed to connect the Fn and TK domains. The unknown structures of the β ID region at the N-terminal of the β Fn1 domain and the C-terminal β -domain joined to the TK domains have not been modelled.

Detailed Description of the Invention

The invention includes new 3D structures for dimeric two state-receptors that are activated or inhibited by ligand binding. It also includes aspects such as the ligand binding site, binding domains, other functional or structural domains and the mechanism of action
15 of the receptors. The invention also includes methods of using these aspects to identify compounds capable of modulating (agonizing or antagonizing) the receptors.

In one embodiment, the receptor is the insulin receptor (amino acid sequence is shown in figure 12). In a preferred embodiment the structure is the fitted quaternary structure of IR. The "fitted quaternary structure" of IR includes the structure of the IR
20 domains fitted together to arrive at a three-dimensional arrangement that fits into the corresponding portion of the quaternary structure of IR. Parts of the fitted quaternary structure are also useful in the methods of the invention. Prior to this invention, the 3D structure of the receptor and its mechanism of activity were unknown. The relative positions of amino acids which bound insulin and provided receptor activity were also
25 poorly understood. The invention details the atomic interactions of insulin with the dimeric insulin receptor (IR) in the extracellular insulin binding site of the receptor. Furthermore, a mechanism is detailed which shows how this binding of insulin results in transmembrane signalling to activate the intracellular intrinsic tyrosine kinase of the insulin receptor dimer. The structure and mechanism explain the normal function of the insulin receptor as well as

the effect of mutations and of altered physiological conditions. The invention provides the first comprehensive description of insulin binding to insulin receptor and the mechanical mechanism of insulin receptor activity. The structure of IR has been determined while complexed to ligands (including insulin) and has been modeled in the insulin-free state.

5 The invention includes the structure of insulin receptor fitted with the atomic coordinates of the amino acids comprising the receptor, the use of that structure to solve the structure of insulin receptor isoforms, homologues and other forms of insulin receptor, mutants and co-complexes of insulin receptor, and the use of the insulin receptor structure and that of its isoforms, homologues, mutants, and co-complexes to
10 design modulators. The structure is particularly useful for development of ingestible (preferably oral) insulin mimicking agents (analogs, mimetics) that can be used in place of insulin (which has to be administered by injection) to treat insulin-dependent diabetes.

 In one aspect the present invention is directed to the three-dimensional structure of an isolated and purified IR polypeptide and its structure coordinates. Another aspect
15 of the invention is to use the structure coordinates of the insulin receptor to reveal the atomic details of the ligand binding site and one or more of the accessory binding sites of insulin receptor such as a cam. The entire receptor may be used or particular regions of interest may be used. Structural and conformational changes induced in the receptor may also be studied. Another aspect of the invention is to use the structure coordinates of an
20 insulin receptor to solve the structure of a different insulin receptor or a mutant, homologue or co-complex of insulin receptor. A further aspect of the invention is to provide insulin receptor mutants characterized by one or more different properties compared to wild-type insulin receptor. Another aspect of this invention is to use the structure coordinates and atomic details of insulin receptors or mutants or homologues or
25 co-complexes thereof to design, evaluate (preferably computationally), synthesize and use modulators of insulin receptor that prevent or treat the undesirable pathologies of inadequately or improperly functioning insulin receptor.

 The IR structure of the present invention includes the three dimensional structure of the receptor including the fitted quaternary structure. The IR structure includes the

ligand binding site that includes the amino acid residues listed in Table 1 and the cam structures including the amino acid residues in Table 2.

This invention also provides the first rational drug design strategy for modulating IR activity. It includes methods for identifying compounds that can interact with insulin receptor. The method for identifying insulin mimetics and insulin antagonists preferably include fitting the crystal structures, NMR structures and other structures of insulin receptor domains into the quaternary structure of the complete insulin-bound dimeric insulin receptor determined from electron microscopic image reconstruction. These interactions can be easily identified by comparing the structural, chemical and spatial characteristics of a test compound to the three dimensional structure of the insulin receptor. Since the amino acids that are responsible for receptor activity and binding were identified by this invention, drug design may be done on a rational basis. Structures such as a cam or a ligand binding site may be studied together or separately. Fragments of a cam or a ligand binding site may also be studied (e.g. at least one or at least 2 of the amino acids in table 1 or 2, optionally also including one or more proximate amino acids).

The structure serves as a detailed basis for the design and testing of insulin analogs, mimetics and insulin antagonists, initially in the computer, but also *in vitro* in cell culture and *in vivo*, providing a method for identifying modulators (antagonists and agonists) having specific contacts with the insulin receptor or an isoform, homologue, mutant or co-complex. The effect of a modification to insulin may be readily viewed on a computer, without the need to synthesize the compound and assay it *in vitro*. As well, non-protein organic molecules may also be compared to the insulin receptor on a computer. One can readily determine if the molecules have suitable structural and chemical characteristics to interact with, and activate or inhibit, receptor activity. The invention includes the IR modulators discovered using all or part of an IR structure of the invention (preferably the fitted quaternary structure) and the methods of the invention.

Drug design

The determination of the quaternary structure of IR, and in particular its fitted quaternary structure, provides a basis for the design of new and specific compounds for

the diagnosis and/or treatment of IR-related pathologies ("pathology" includes a disease, a disorder and/or an abnormal physical state preferably characterized by either (i) inadequate or excessive insulin in a mammal (preferably a human) or inadequate or excessive IR activity. IR related pathologies include those involving IR as in fig. 12 or IR variants described in this application.). This structure is useful in the design of modulators (agonists or antagonists), which may be used as therapeutic or prophylactic compounds for treating pathologies in which upregulation or downregulation of receptor activity is beneficial. It will be apparent that methods using IR described below may be readily adapted for use with a fragment of IR or an IR variant.

The characterization of the novel IR ligand binding site and cams permit the design of potent, highly selective IR modulators. Several approaches can be taken for the use of the IR structure in the rational design of ligands of IR. A computer-assisted, manual examination of a ligand binding site or cam structure may be done.

This invention includes the methods for identifying modulators of IR that act on the IR quaternary structure (preferably the fitted quaternary structure), ligand binding site and/or cam, as well as the modulators themselves. The agonist modulators upregulate IR activity by biasing IR towards its active, closed conformation. The antagonist modulators downregulate IR activity by biasing IR towards its inactive, open conformation. Such modulators may bind to all or a portion of the ligand binding site of IR. They may also modulate IR activity by interacting with other portions of IR, such as the cam structures. They may be competitive or non-competitive modulators. Once identified and screened for biological activity, these modulators may be used therapeutically or prophylactically to affect IR activity.

The invention also includes methods of agonizing or antagonizing insulin receptor by administering compounds with structural and chemical properties that allow the compounds to interact with insulin receptor residues in order to modulate receptor activity.

Interaction of modulators of IR ligand binding site

A test compound that is a modulator interacts with at least one insulin receptor residue listed in Table 1 on monomer A and at least one residue in Table 1 on monomer B in order to activate or inhibit insulin receptor. "Interact" refers to binding to the receptor which is capable of modulating its activity. Receptor fragments may be used in the methods of the invention to predict how the full receptor will react to a modulator. Since the IR is a 2-fold symmetric dimer structure, either one of the IR monomers can represent monomer A, the other representing monomer B. A modulator that is an agonist is capable of changing the IR from an inactive conformation to an active conformation. A modulator that is an antagonist is capable of changing the IR from an active conformation to an inactive conformation (or may keep or maintain IR in its inactive conformation). A modulator may bias the receptor towards a particular conformation instead of (or in addition to) changing the conformation.

The compound may also interact with at least: two, three, or four or five of the residues on each of monomer A or monomer B that are listed in Table 1. The test compound may interact with at least about: five, six, seven or eight, nine, ten, eleven or twelve amino acid residues on monomer B. The intersidechain distances between the modulator and the IR are preferably about those distances (or at least one of the distances) listed in Table 1. The distances may be varied by plus or minus about: 0.1A, 0.2A, 0.25A, 0.3A, 0.4A, 0.5A, 0.6A, 0.7A, 0.75A, 0.8A, 0.9A, 1A or >1A, >1.5A or 2A as long as the test compound is still able to interact with IR and modulate its activity. It is apparent that the test compound must be able to make appropriate interactions with the IR ligand binding site if it is to activate the IR.

Table 1

Modeled Approaches between Insulin Side Chains and Insulin Receptor Side Chains

‡ Potential vicinal interactions are grouped

† Minimum distance of approach modelled at 2.5 Å

* Closest approach; interaction would require a water molecule, hydrogen bond chain or a rotation of the entire L2 region

Individual amino acids in insulin that are important in binding to the receptor include: A1, A4, A5, A19, A21, B12, B16, B17, B24, B25 and B26. On the insulin receptor amino acids that are involved in insulin binding include: 12, 14, 15, 34, 36, 39, 64, 86 89, 90, 91, 243-251, 323 and 707-716. Only amino acids 707-716 are not in the L1-CR-

L2 domains. All others are either in the walls lining the ligand binding site tunnel or are at the entrance of the ligand binding site.

Interaction of modulators of IR cam

The invention also provides alternative and new methods to modulate IR activity. For example, the 3D structure shows that IR has two "cams" that change the conformation of the IR from an inactive conformation to an active conformation. The existence of these cams was unknown prior to this invention. Modulators such as organic molecules (protein or non-protein) may block or activate cam movements in order to modulate the IR toward an inactive state or to an active state.

A modulator interacts with at least one insulin receptor residue listed in Table 2 on the Cam-loop segment of the Cys-rich region and at least one residue in Table 2 on the L1 surface proximate the cam-loop segment in order to activate or inhibit insulin receptor. The modulator is capable of changing the IR from an inactive conformation to an active conformation and/or biasing IR towards an active or inactive conformation.

The compound may also interact with at least: two, three, four, five or six (or seven, eight, nine, ten, eleven or twelve) of the residues listed in Table 2 on each of the Cam-loop segment of the Cys-rich region and the L1 surface proximate the cam-loop segment. The intersidechain distances between the test compound and the IR may be varied by plus or minus about: 0.1A, 0.2A, 0.25A, 0.3A, 0.4A, 0.5A, 0.6A, 0.7A, 0.75A, 0.8A, 0.9A, 1A or >1A, >1.5A or 2A as long as the test compound is still able to interact with IR and modulate its activity. It is apparent that the modulator must be able to make appropriate interactions with the IR cam if it is to activate or inactivate the IR.

Table 2

Charged and polar amino acids in the region of the cam-loop can bind a modulator to the receptor, to allow specificity of binding, and to move or block the Cam-loop segment.

All specific interactions with the amino acids below would be electrostatic (ionic) except with Gln (glutamine) and Asn (asparagine) which are polar.

Cam-loop segment of Cys-rich region		L1 surface near cam-loop segment	
Lys265	electrostatic	Glu1 NH ₃ ⁺	electrostatic
Lys267	electrostatic	Asn15	polar
Asn268	polar	Asn16	polar
Arg270	electrostatic	Arg19	electrostatic
Arg272	electrostatic	Glu22	electrostatic
Glu273	electrostatic	Glu24	electrostatic
		Asn25	polar
		Glu44	polar
		Asp45	electrostatic
		Arg47	electrostatic
		Asp48	electrostatic
		Lys53	electrostatic

The invention includes a method of agonizing or antagonizing IR activity by administering a modulator identified according to the methods of the invention.

IR modulating compounds

5 A diagnostic or therapeutic modulating compound of the present invention can be, but is not limited to, at least one selected from a nucleic acid, a compound, a protein, a lipid, a saccharide, an isotope, a carbohydrate, an imaging agent, a lipoprotein, a glycoprotein, an enzyme, a detectable probe, and antibody or fragment thereof, or any combination thereof. Diagnostic compounds (useful in diagnosis as a research tool in an
10 assay) can be detectably labeled as for labeling antibodies. Such labels include, but are not limited to, enzymatic labels, radioisotope or radioactive compounds or elements, fluorescent compounds or metals, chemiluminescent compounds and bioluminescent compounds. Other types of compounds may also be useful.

The compound may include an amino acid sequence (including a peptide, a
15 polypeptide or a protein) or an amino acid sequence derivative (ie an analog, prepared for

example by substituting, deleting, modifying (eg. glycosylating) one or more amino acids - see, for example, US Patent Nos. 5,952,297, 5,922,675, 5,700,662, 5,693,609, 5,646,242, 5,149,777, 5,00,8241, 4,946,828 and 5,164,366. The analog may also be part of a human insulin analog complex, such as that in US 5,474,978.).

5 The analog may be an insulin derivative, an insulin precursor derivative or a derivative of an already known insulin analog (See for example US Patent Nos. 5,952,297, 5,922,675, 5,747,642, 5,716,927). One skilled in the art may analyze insulin, its precursors, and other known analogs to determine how they interact with IR and then prepare improved compounds.

10 Those of skill in the art recognize that a variety of techniques are available for constructing derivatives with the same or similar desired biological activity insulin but with more favorable activity than the polypeptide with respect to route of administration, solubility, stability, and/or susceptibility to hydrolysis and proteolysis. See, for example, Morgan and Gainor, *Ann. Rep. Med. Chem.*, 24:243-252 (1989). Examples of
15 polypeptide derivatives are described in U.S. Patent Nos. 5,643,873. Other patents describing how to make and use derivatives include, for example, 5,786,322, 5,767,075, 5,763,571, 5,753,226, 5,683,983, 5,677,280, 5,672,584, 5,668,110, 5,654,276, 5,643,873. Derivatives may be designed on computer by comparing compounds to the 3D structures disclosed in this application. Derivatives of insulin may also be made according to other
20 techniques known in the art. For example, by treating a polypeptide of the invention with an agent that chemically alters a side group by converting a hydrogen group to another group such as a hydroxy or amino group. Derivatives can include sequences that are either entirely made of amino acids or sequences that are hybrids including amino acids and modified amino acids or other organic molecules.

25 The compound may also be a nonprotein organic molecule, such as a mimetic (ie a non-protein molecule which functionally mimics a peptide, polypeptide or a protein). For example, a mimetic may functionally mimic insulin by binding to IR and activating it. Such a mimetic may activate IR to a greater or lesser extent than that caused by

insulin as long as the mimetic produces the end result of IR activation. Examples of mimetics are pyrrolidine compounds such as (2R,3R,4R)-3,4-dihydroxy-2-hydroxymethylpyrrolidine and other substituted 2-methylpyrrolidines (eg. US No. 5,854,272) or hydroxy alkyl piperidine (eg. US No. 5,863,903). Small organic molecules
5 may also be used to antagonize or agonize IR by interacting with a cam.

A compound can have a therapeutic effect on the target cells, the effect one of those known to be caused by modulation of IR. The therapeutic effects that modulates at least one IR in a cell can be provided by therapeutic agent delivered to a target cell via pharmaceutical administration (discussed below).

10 *Determining suitable types of modulators from IR structure*

One skilled in the art would recognize, in view of the fitted quaternary structure of IR, that the type of modulator used may be varied or customized according to the portion of IR targeted. For example, modulators may be simple peptides which take advantage of specific hydrophilic, hydrophobic, or charge interactions, or variously branched peptides
15 with each branch differentially contributing to a particular interaction (such as the lologomer structures of Gariepy and co-workers: PNAS USA 92, 2056-60, 1995; Bioconjugate Chem. 10, 745-54, 1999). Modulators may be simpler chemicals with corresponding interaction sites, in or near the insulin binding contact sites of IR. Such agents may also be molecules that act external to the insulin binding site to effect activation or inhibition by interacting
20 with specific sites identified as important in the mechanism of transmembrane signal transduction. These include specific chemicals, peptides or monoclonal and polyclonal antibodies or subantibody fragments such as the Fab, or Fv fragments. They include molecules that specifically remove or enhance the natural blockage on the insulin receptor to activation of its intrinsic tyrosine kinase. Such agents may also be molecules that
25 enhance or inhibit transphosphorylation of the juxtaposing intrinsic pair of tyrosine kinase domains of the dimeric insulin receptor.

Determining structure of IR, IR variants and other receptors

Complete IR Structure

Techniques described in this application (such as those in references 4 and 5 or US 5,834,228) were used to identify and characterize regions of an insulin receptor such as the LI-Cys-rich-L2 domain. We characterize the entire insulin receptor and its ligand binding site using these techniques. The fitted quaternary structure of IR needed for drug design is disclosed in this application. We characterize the regions which are not fully characterized by x-ray crystallography or nuclear magnetic resonance spectroscopy of small domains that include these structures. They include the transmembrane and juxtamembrane domains, the beta insert and the beta C-terminal regions (see legend to fig. 6).

IR Variants and Other Receptors

The IR data of the invention may be also used to solve the structure of IR variants (eg. mutants, homologs) or other dimeric receptors, or of the any other protein with significant amino acid sequence homology to any functional or structural domain of IR. We determine the structure of isoform A and B of IR as well as mutants. IR has two isoforms, A and B. Isoform A is shorter than isoform B by 12 amino acids which are coded by exon 11 of the IR gene (the twelve amino acids are from Lys718 to Arg 729 as follows: Lys-Thr-Ser-Ser-Gly-Thr-Gly-Ala-Glu-Asp-Pro-Arg). Isoform A interacts with insulin and produces the same effect as isoform B, which is a metabolic effect.

The insulin receptor described in this application was extracted from human placenta. Insulin receptor from other sources, such as other tissues, cells or cDNA may also be modeled and used in the methods of the invention. The techniques described in this application to image the receptor may be used with insulin receptor from any human, mammalian or other tissue. Insulin receptor homologues and other forms of insulin receptor, mutants and co-complexes of insulin receptor may also be used. A fragment of the receptor may also be used. A fragment may be from about 25-50, about 50-100, about 100-250 or about 250-500, 500-1000 or at least about 1000 amino acids.

The IR is similar to other dimeric receptors, such as IGFR and IRR. The 3D structure of IR may be used to determine the 3D structure of these receptors by identifying regions of homology (similarity between amino acid, secondary, tertiary or quaternary structure) between the receptors and determining the structure of the dimeric receptor.

One useful method for this purpose is molecular replacement in crystallography. In this method, the unknown structure in a crystal, whether it is another form of IR, an IR mutant, or the structure of some other dimeric receptor with significant amino acid sequence homology to any functional domain of IR, may be determined using the IR structure coordinates of the IR dimer structure coordinates of this invention.. This method will provide an accurate structural form for the unknown structure more quickly and efficiently.

Computer based design

The invention allows computational screening of molecule data bases for compounds that can bind in whole, or in part, to IR. The IR structure of the invention permits the design and identification of synthetic compounds and/or other molecules which have a shape complimentary of the conformation of the IR ligand binding site of the invention. Using known computer systems, the coordinates of the IR structure of the invention may be provided in machine readable form, the test compounds designed and/or screened and their conformations superimposed on the complementary surface structures and surface characteristics of the receptor or of its binding site. Subsequently, suitable candidates identified as above may be screened for the desired activity, stability, and other characteristics.

In this screening, the quality of fit of such entities or compounds to the binding site may be judged either by shape complementary (R.L DesJarlais et al. J. Med. Chem 31:72-729 (1988) or by estimated interaction energy (E.C. Meng et al, J. Comp. Chem. 13: 505 - 524 (1992)).

Thus, the IR structure permits the screening of known molecules and/or the designing of new molecules which bind to the IR structure, particularly at the ligand binding site or cams, via the use of computerized evaluation systems. For example, computer modeling systems are available in which the sequence of the IR, and the IR structure (i.e., atomic coordinates of IR and/or the atomic coordinate of the ligand binding site cavity, bond angles, dihedral angles, distances between amino acids in the ligand binding site region, etc. as provided by the fitted quaternary structure may be input. A machine readable medium may be encoded with data representing the coordinates of the entire IR structure. The computer then generates structural details of the site into which a test compound should bind, thereby enabling the determination of the complementary structural details of said test compound.

The production of compounds that bind to or modulate IR generally two factors. First, the compound must be capable of physically and structurally associating with IR. Non-covalent molecular interactions important in the association of IR with its substrate include hydrogen bonding, ionic interactions van der Waals interactions and hydrophobic interactions.

The invention permits the design of agents that bind to the three dimensional surfaces of IR by using the pattern on those surfaces of positive charges, negative charges, hydrophobic grouping of atoms, dipolar groups and hydrodren bonds that are revealed in the structure of the surfaces and in the relative positioning of these surfaces with respect to each other in the quaternary structure.

Those skilled in the art can create an agent that places the positions of chemical groups on the agent near matching atoms or groups of atoms on IR using well-known interactions such those as in Table3.

Table 3

Characteristics of atoms or
groups of atoms on IR

- hydrogen donor
- hydrogen acceptor
- positive charge
- hydrophobic group
- polar group
- hydrogen acceptor
- hydrogen donor

5 Second, the compound must be able to assume a conformation that allows it to associate with IR. The compound will preferably interact with the ligand binding site or a cam and bias or change IR towards either an active conformation or inactive conformation. Although certain portions of the compound will not directly participate in
10 this association with IR those portions may still influence the overall conformation of the molecule. This, in turn, may have a significant impact on potency. Such conformational requirements include the overall three-dimensional structure and orientation of the chemical entity or compound in relation to all or a portion of the binding site, e.g., ligand binding site, accessory binding site, or cam of IR or the spacing between functional
15 groups of a compound comprising several chemical entities that directly interact with IR.

The potential modulating effect of a chemical compound with IR may be estimated prior to its actual synthesis and testing by the use of computer modeling techniques. If the structure of the compound shows insufficient interaction and association between it and IR the compound is not synthesized and tested. If computer
20 modeling indicates a suitable interaction, the molecule may then be synthesized and tested for its ability to bind to IR in an assay. Synthesis of ineffective and inoperative compounds can be avoided.

Computer modeling may be combined with assay techniques. For example, one could probe the IR (or fragments thereof) with a variety of different molecules to
25 determine optimal sites for interaction between candidate modulators and IR. Small molecules that bind tightly to IR sites can be designed and synthesized and tested for their IR modulatory activity. This information can be combined with computer modeling information. A modulating compound may be computationally evaluated. A modulating compound may be further designed by a series of steps in which compounds or fragments

are screened and selected for their ability to associate with the individual binding amino acids, secondary, tertiary or quaternary structure or other areas of IR.

One skilled in the art may use one of several methods to screen chemical entities or fragments for their ability to interact with IR. This process may begin generating the ligand binding site on the computer screen based on the IR amino acids and distances from the co-ordinates of the IR complex. Selected fragments or chemical entities are then be positioned against IR. Docking may be accomplished using software such as Insight, Quanta, and Sybyl, followed by energy minimization and molecular dynamics with standard molecular mechanics forcefields, such as CHARMM and AMBER.

Specialized computer programs may also assist in the process of selecting fragmented or chemical entities. These include:

MCSS (Molecular Simulations, Burlington, MA) [A. Miranker and M. Karplus. "Functionality Maps of Binding Sites: A Multiple Copy Simultaneous Search Method". Proteins: Structure, Function and Genetics, 11:29-34 (1991)].

GRID (Oxford University, Oxford, UK) [P.J. Goodford, "A Computational Procedure for Determining Energetically Favorable Binding Sites on Biologically Important Macromolecules". J. Med. Chem. 28:849-857 (1985)].

DOCK (University of California, San Francisco, CA) [I.D. Kuntz et al, "A Geometric Approach to Macromolecule-Ligand Interactions", J. Mol. Biol. 161: 269-288 (1982)].

AUTOCOCK (Scripps Research Institute, La Jolla, CA) [D.S. Goodsell and A.J. Olsen, "Automated Docking of Substrates to Proteins by Simulated Annealing". Proteins: Structure, Function, and Genetics, 8:192-202 (1990)].

Additional commercially available computer databases for small molecular compounds include Cambridge Structural Database and Fine Chemical Database. For a review see Rusinko, A., Chem. Des., Auto. News 8.44-47 (1993).

For example, software such as GRID (a program that determines probable interaction sites between probes with various functional group characteristics and the enzyme surface) analyzes the ligand binding site to determine structures of modulating compounds. The program calculates, with suitable activating or inhibiting groups on molecules (e.g. protonated primary amines as the probe) suitable conformations. The program also identifies potential hot spots around accessible positions at suitable energy contour levels. Suitable ligands, such as inhibiting or activating compounds or compositions, are then tested for modulating IR.

Once suitable chemical entities or fragments have been selected, they can be assembled into a single compound. Assembly may be proceeded by visual inspection of the relationship of the fragments to each other on the three-dimensional image displayed on a computer screen in relation to the structure coordinates of IR. This would typically be followed by manual model building using software such as Quanta or Sybyl.

Useful programs to aid one of skill in the art in connecting the individual chemical entities or fragments include:

3D Database systems such as MACCS-3D (MDL Information Systems, San Leandro, CA). See Y.C. Martin, "3D Database Searching in Drug Design", J.Med. Chem., 35:2145-2154 (1991).

CAVEAT (University of California, Berkeley, CA) [P.A. Barlett et al. "CAVEAT: A program to Facilitate the Structure Derived design of Biologically Active Molecules," in Molecular Recognition in Chemical and Biological Problems," Special Pub., Royal Chem. Soc. 78, pp 182-196 (1989).

HOOK (Molecular Simulations, Burlington, MA). Instead of proceeding to build IR modulator in a step-wise fashion one fragment or chemical entity at a time as described above, inhibitory or other type of binding compounds may be designed as whole or "de novo" using either an empty ligand binding site or optionally including some portion(s) of a known compound(s). These methods include:

LUDI (Biosym Technologies, San Diego, CA) [H.-J. Bohm, "The Computer Program LUDI: A New method for the De Novo Design of Enzyme Inhibitors", J. Comp. Aid Molec. Design, 6:61-78 (1992)].

LeapFrog (Tripos Associates, St. Louis, MO). Other molecular modeling
5 techniques may also be used. For example, N.C. Cohen et al. "Molecular Modeling
Software and Methods for Medicinal Chemistry". J. Med. Chem., 33:883-894 (1999).
M.A. Navia and M. A. Murcko, "The Use of Structural Information in Drug Design",
Current Opinions in Structural Biology, 2:202-210 (1992). For example, where the
structures of test compounds are known, a model of the test compound may be
10 superimposed over the model of the structure of the invention. Numerous methods and
techniques are known in the art for performing this step, any of which may be used. See,
e.g., P.S. Farmer, Drug Design, Ariens, E.J., ed., Vol. 10, pp 119-143 (Academic Press,
New York, 1980); U.S. Patent No. 5,331,573; U.S. Patent No. 5,500,807; C. Verlinde,
Structure, 2:577-587 (1994); and I.D. Kuntz, Science, 257:1078-1082 (1992). The model
15 building techniques and computer evaluation systems described herein are not a
limitation on the present invention.

LEGEND (Molecular Simulations, Burlington, MA) [Y. Nishibata and A. Itai,
Tetrahedron, 47:8985 (1991)].

Using these computer evaluation systems, a large number of compounds may be
20 quickly and easily examined and expensive and lengthy biochemical testing avoided.
Moreover, the need for actual synthesis of many compounds is effectively eliminated.

***Apparatus including the IR fitted quaternary structure or other IR structural
information***

Storage media for the IR fitted quaternary structure or other IR structural
25 information include, but are not limited to: magnetic storage media, such as floppy discs;
hard disc storage medium, and magnetic tape; optical storage media such as optical discs
or CD-ROM; electrical storage media such as RAM and ROM; and hybrids of these
categories such as magnetic/optical storage media. Any suitable computer readable

mediums can be used to create a manufacture comprising a computer readable medium having recorded on it an amino acid sequence and/or data of the present invention.

“Recorded” refers to a process for storing information on computer readable medium. A skilled artisan can readily adopt any of the presently know methods for recording information on computer readable medium to store an amino acid sequence, nucleotide sequence and/or EM data information of the present invention.

A variety of data storage structures are available to a skilled artisan for creating a computer readable medium having recorded thereon an amino acid sequence and/or data of the present invention. The choice of the data storage structure will generally be based on the means chosen to access the stored information. In addition, a variety of data processor programs and formats can be used to store the sequence and data information of the present invention on computer readable medium. The sequence information can be represented in a word processing text file, formatted in commercially-available software such as WordPerfect and MicroSoft Word, or represented in the form of an ASCII file, stored in a database application, such as DB2, Sybase, Oracle, or the like. A skilled artisan can readily adapt any number of data processor structuring formats (e.g. text file or database) in order to obtain computer readable medium having recorded thereon the information of the present invention.

By providing the sequence and/or data on computer readable medium and the structural information in this application, a skilled artisan can routinely access the sequence and data to model a receptor a subdomain thereof, or a ligand thereof. As described above, computer algorithms are publicly and commercially available which allow a skilled artisan to access this data provided in a computer readable medium and analyze it for molecular modeling or other uses.

The present invention further provides systems, particularly computer-based systems, which contain the sequence and/or data described herein. Such systems are designed to do molecular modeling for an IR or at least one subdomain or fragment thereof.

As used herein, "a computer-based system" refers to the hardware means, software means, and data storage means used to analyze the sequence and/or data of the present invention. The minimum hardware means of the computer-based systems of the present invention comprises a central processing unit (CPU), input means, output means, and data storage means. A skilled artisan can readily appreciate which of the currently available computer-based system are suitable for use in the present invention.

As stated above, the computer-based systems of the present invention comprise a data storage means having stored therein our IR or fragment sequence and/or data of the present invention and the necessary hardware means and software means for supporting and implementing an analysis means. As used herein, "data storage means" refers to memory which can store sequence or data (coordinates, distances, quaternary structure etc.) of the present invention, or a memory access means which can access manufactures having recorded thereon the sequence or data of the present invention.

As used herein, "search means" or "analysis means" refers to one or more programs which are implemented on the computer-based system to compare a target sequence or target structural motif with the sequence or data stored within the data storage means. Search means are used to identify fragments or regions of an IR which match a particular target sequence or target motif. A variety of known algorithms are disclosed publicly and a variety of commercially available software for conducting search means are and can be used in the computer-based systems of the present invention. A skilled artisan can readily recognize that any one of the available algorithms or implementing software packages for conducting computer analyses that can be adapted for use in the present computer-based systems.

As used herein, "a target structural motif," or "target motif," refers to any rationally selected sequence or combination of sequences in which the sequences(s) are chosen based on a three-dimensional configuration or electron density map which is formed upon the folding of the target motif. There are a variety of target motifs known in the art. Protein targets include, but are not limited to, ligand binding sites, structural

subdomains, epitopes, and functional domains. A variety of structural formats for the input and output means can be used to input and output the information in the computer-based systems of the present invention.

One application of this embodiment is provided in Figure 13. This figure
5 provides a block diagram of a computer system 5 that can be used to implement the present invention. The computer system 5 includes a processor 10 connected to a bus 15. Also connected to the bus 15 are a main memory 20 (preferably implemented as random access memory, RAM) and a variety of secondary storage memory 25 such as a hard drive 30 and a removable storage medium 35. The removable medium storage device 35
10 may represent, for example, a floppy disk drive, A CD-ROM drive, a magnetic tape drive, etc. A removable storage unit 40 (such as a floppy disk, a compact disk, a magnetic tape, etc.) containing control logic and/or data recorded therein may be inserted into the removable medium storage medium 35. The computer system 5 include appropriate software for reading the control logic and/or the data from the removable
15 medium storage device 35 once inserted in the removable medium storage device 35. A monitor 45 can be used as connected to the bus 15 to visualize the structure determination data.

Amino acid, encoding nucleotide or other sequence and/or data of the present invention may be stored in a well known manner in the main memory 20, any of the
20 secondary storage devices 25, and/or a removable storage device 40. Software for accessing and processing the amino acid sequence and/or data (such as search tools, comparing tools, etc.) reside in main memory 20 during execution.

One or more computer modeling steps and/or computer algorithms are used as described above to provide a molecular 3-D model, preferably showing the fitted
25 quaternary structure, of a cleaved dimeric receptor, using amino acid sequence data and atomic coordinates for the receptor. The structure of other dimeric receptors such as IGFR and IRR may be readily determined using methods of the invention and the present knowledge of these receptors.

Assays of modulators identified from IR structure

Once identified, the modulator may then be tested for bioactivity using standard techniques (eg. *in vitro* or *in vivo* assays). For example, the compound identified by drug design may be used in binding assays using conventional formats to screen agonists (eg
5 by measuring *in vivo* or *in vitro* binding of receptor to insulin after addition of a compound). One assay is the fat cell assay for glucose uptake and oxidation which is known in the art. Experiments may also be done with whole diabetic animals. Suitable assays include, but are not limited to, the enzyme-linked immunosorbent assay (ELISA), or a fluorescence quench assay. In evaluating IR modulators for biological activity in
10 animal models (e.g. rat, mouse, rabbit), various oral and parenteral routes of administration are evaluated. Using this approach, it is expected that modulation of an IR occurs in suitable animal models, using the ligands discovered by molecular modeling.

Once identified and screened for biological activity, these inhibitors may be used therapeutically or prophylactically to modulate IR activity as described below.

Pharmaceutical/diagnostic formulations of modulators identified from quaternary structure, methods of medical treatment and uses

Modulating IR in a Cell

The present invention also provides a method for modulating the activity of the IR in a cell using IR modulating compounds or compositions of the invention. In general,
20 compounds (antagonists or agonists) which have been identified to inhibit or enhance the activity of IR can be formulated so that the agent can be contacted with a cell expressing a IR protein *in vivo*. The contacting of such a cell with such an agent results in the *in vivo* modulation of the activity of the IR proteins. So long as a formulation barrier or toxicity barrier does not exist, agents identified in the assays described above will be effective for
25 *in vivo* and *in vitro* use. These modulators may be used in therapies that are beneficial in the treatment of diabetes and other diseases, disorders and abnormal physical states characterized by improper or inadequate insulin receptor activity. Even if receptor

activity is normal, there may be therapeutic benefit in upregulating or downregulating its activity in some circumstances.

Medical Treatments and Uses

Diseases, disorders and abnormal physical states that may be treated by IR agonists include diabetes and hyperglycemia. Diseases, disorders and abnormal physical states that may be treated by IR antagonists include hypoglycemia.

Isoform A of IR is shorter than isoform B by 12 amino acids which are coded by exon 11 of the IR gene. Isoform A interacts with insulin and produces the same effect as isoform B, which is a metabolic effect. Isoform A acts as an IGF-2 receptor which may be important in the growth of cancer cells (Frasca, F, Pandini, G, Scalia, P, Sciacca, L, Mineo, R, Costantino, A, Goldfine, ID, Delfiore, A, Vigneri, R, 1999, Insulin receptor isoform A: A newly recognized high affinity insulin like growth factor II receptor in situ and cancer cells. Molecular and Cellular Biology 19:5 pg. 3278-3288.). IGF-2 acts on isoform A to produce a growth effect via IR rather than just a metabolic effect. The quaternary structure of isoform A is very similar to isoform B and can be readily determined according to the information in this application. IGF I binds to both isoforms with low affinity (1/10) and also produces a growth effect (less significant because of the low affinity binding). One may design an antagonist of isoform A that does not interact with isoform B (or at least has lower affinity binding to isoform B) to inhibit cancer cell growth in response to IGF-2.

Pharmaceutical Compositions

Modulators may be combined in pharmaceutical compositions according to known techniques. The compounds of this invention are preferably incorporated into pharmaceutical dosage forms suitable for the desired administration route such as tablets, dragees, capsules, granules, suppositories, solutions, suspensions and lyophilized compositions to be diluted to obtain injectable liquids. The dosage forms are prepared by conventional techniques and in addition to the compounds of this invention could contain solid or liquid inert diluents and carriers and pharmaceutically useful additives such as

lipid vesicles liposomes, aggregants, disaggregants, salts for regulating the osmotic pressure, buffers, sweeteners and colouring agents. Slow release pharmaceutical forms for oral use may be prepared according to conventional techniques. Other pharmaceutical formulations are described for example in US 5,192,746.

5 Pharmaceutical compositions used to treat patients having diseases, disorders or abnormal physical states could include a compound of the invention and an acceptable vehicle or excipient (Remington's Pharmaceutical Sciences 18th ed, (1990, Mack Publishing Company) and subsequent editions). Vehicles include saline and D5W (5% dextrose and water). Excipients include additives such as a buffer, solubilizer,
10 suspending agent, emulsifying agent, viscosity controlling agent, flavor, lactose filler, antioxidant, preservative or dye. The compound may be formulated in solid or semisolid form, for example pills, tablets, creams, ointments, powders, emulsions, gelatin capsules, capsules, suppositories, gels or membranes. Routes of administration include oral, topical, rectal, parenteral (injectable), local, inhalant and epidural administration. The
15 compositions of the invention may also be conjugated to transport molecules to facilitate transport of the molecules. The methods for the preparation of pharmaceutically acceptable compositions which can be administered to patients are known in the art.

 The pharmaceutical compositions can be administered to humans or animals. Dosages to be administered depend on individual patient condition, indication of the
20 drug, physical and chemical stability of the drug, toxicity, the desired effect and on the chosen route of administration (Robert Rakel, ed., Conn's Current Therapy (1995, W.B. Saunders Company, USA)).

Example 1 - Determination of the 3D structure of IR

Preparation of IR

25 Insulin receptor protein (HIR) was solubilized from human placental membranes and purified by affinity chromatography on an insulin column (9) followed by further FPLC purification on Sephacryl S-200. The purity of HIR was better than 95% by sodium dodecyl sulfate polyacrylamide gel electrophoresis. HIR was incubated with NG-BI (final

concentration of $\sim 0.5 \times 10^{-6}$ M) at 4° C overnight in 20 mM HEPES buffer (pH 7.5) at a molar ratio of insulin:HIR of $\sim 10:1$. Free NG-BI was removed by microfiltration with a cut-off of 300 kDa (Sigma). The mixture was diluted to 7.5 μ g of receptor protein/ml with 20 mM HEPES buffer, pH 7.5, prior to loading on the grid.

5 *Preparation of Specimen for STEM*

The specimen (5 μ l) was injected into 5 μ l of the dilution buffer on 300-mesh copper grid coated with a holey plastic film overlaid with a carbon film 23 Å thick, washed with HEPES buffer and 10 mM ammonium acetate (pH 7.5). The grid was drained by wicking with filter paper, leaving a very thin solution layer, then immediately quick-frozen
10 by plunging into liquid ethane at -150°C. The frozen specimen was transferred at liquid nitrogen temperature into the STEM (Vacuum Generators, Model HB601UX) and freeze-dried at -140° C in the STEM cold-stage. Images in a 480 x 480 pixel format were acquired with the specimen at -150°C using cold field emission at 100 kV, a dose of 6e/Å² and a pixel size of 6.5 Å. The beam size was 3Å. Inelastic and annular dark field signals were
15 detected simultaneously.

Nanogold Marking

The quaternary structure of IR bound to insulin was determined by marking with Nanogold. The 70 atom gold marker localized and delimited the insulin binding site. Compared to native bovine insulin, Nanogold-bovine-insulin (NG-BI), derivatized at the B-
20 chain Phe1(5), a location not directly involved in receptor binding (6), bound to human insulin receptor (HIR) with only a slightly reduced affinity (Fig. 1). Purified solubilized HIR used in this study has been shown to be fully active (7). Such HIR, incubated with NG-BI to form the HIR/NG-BI complex in the absence of ATP, was subjected to low-dose dark field STEM imaging at -150° C. Figure 2A shows a representative field of individual
25 molecules. On average, each HIR/NG-BI complex measured 15 nm across. Based on its strong scattering, the 1.4 nm gold ligand of NG-BI was located on the image directly as a clear site of highest density, or could be demonstrated as such by thresholding. Figure 2B shows examples of molecules with 1 or 2 sites of highest density, indicative of binding of one or occasionally two NG-BI particles, consistent with the known binding of between one

and two insulins per IR (3). When two NG-BI particles were detected, they were in close proximity to each other.

Image Reconstruction

Approximately 700 images were selected for reconstruction on the basis of having a definite site of high density, the expected mass for the complex, being structurally contiguous, and being separated from neighbouring images. The 3D reconstructions of the HIR/NG-BI complex are shown in Figure 3. The interpreted alignment and the fit of the biochemical domains to this structure are detailed in Fig. 4. The 3D structure at the full expected volume is compact and globular (Fig. 3A, top panel). The NG-BI particle was located on the 3D reconstruction by increasing the density threshold without imposing symmetry (Fig. 3A, panel 2 and 3), to pinpoint the binding site and to limit the fit of insulin to its vicinity within the IR complex. Since insulin binds to the L1-Cys-rich-L2 regions of the ectodomain of IR, the NG cluster identifies this region of IR in the reconstruction.

Paired elastic and inelastic images were combined to increase the signal-to-noise ratio two-fold. Single particles were interactively selected in 64x64 pixel windows using the program WEB (Wadsworth Laboratories, Albany NY), and low-pass filtered to 1.0 nm using a Gaussian filter in the program SPIDER (Wadsworth Laboratories, Albany NY). The molecular mass was calculated relative to the 23 Å carbon support with a density of 2.0 g/cm³. The particles had a Gaussian mass distribution with a modal mass of 570 kDa, which includes the mass of 480 kDa for the HIR and NG-BI plus the weight for an estimated 150 Triton X-100 molecules. Particle images were "grown" from a central high density in expanding contiguous contour levels to a global cut-off corresponding to the average mass. Relative orientations were computed as before (N. A. Farrow and F. P. Ottensmeyer, *J. Opt. Soc. Am. A* **9**, 1749 (1992); N. A. Farrow and F. P. Ottensmeyer, *Ultramicroscopy* **52**, 141 (1993); G. J. Czarnota, D. W. Andrews, N. A. Farrow, F. P. Ottensmeyer, *J. Structural Biology* **113**, 35 (1994); G. J. Czarnota, D. P. Bazett-Jones, E. Mendez, V. G. Allfrey, F. P. Ottensmeyer, *Micron* **28**, 419 (1997)) and 3D reconstructions were performed by filtered back-projection using an angular distribution-dependent filter. Measurements of resolution were obtained via Fourier shell phase residual calculations

between reconstructions of two independent sets of half of the 704 images each (G.J. Czarnota, D.W. Andrews, N.A. Farrow, F.P. Ottensmeyer, *J. Struct. Biol.* **113**, 35 (1994)). Calculations were carried out on an SGI Indigo workstation (Silicon Graphics Inc., Mountain View, CA). The program IRIS EXPLORER 2.0 (SGI, Mountain View, CA) displayed the 3D reconstructions. To show domain relationships and structural links, the reconstructions were displayed with intermediate densities between 5% and 10% higher than the average density for the full volume. INSIGHT II (Molecular Simulations Inc., San Diego, CA) was used to dock known crystal structures and approximate models. Handedness of the construct was determined by fitting the x-ray crystallographic structure of tyrosine kinase domain into mirror pairs of the 3D reconstruction.

Example 2 - Structural Characteristics of IR

Domain-like features of the structure become evident at intermediate density thresholds (Figure 3A, panel 2), and, except for the NG-BI region, these indicate a strong 2-fold vertical rotational symmetry as anticipated from the dimeric configuration of the oligotetrameric ($\alpha\beta$)₂ structure of IR. This symmetry was used to reduce noise in the reconstructions and render the structures shown in panel 1 and in Figure 3B, as being viewed in the plane of the membrane, and in the extracellular (top) and intracellular (bottom) perspectives. Views of these structures are reminiscent of the X- and Y-shaped electron microscopic images previously observed for IR or its ectodomain.

In the side views, the top part of the structure, where NG is located, is identified as the ectodomain of the α subunit. The dog-bone-shaped substructure of the 3D reconstruction, (Fig. 3B, top view), and equivalently the top-most, bow-tie-shaped structure (Fig. 3B, 0°), are designated as the two L1 domains of the dimeric receptor on the basis of the x-ray structure of the L1-Cys-rich-L2 domains. The side view at 65° shows the L1-Cys-rich-L2 domains as contiguous substructures across the upper central region of the molecule, with enough additional volume in this region to account for most of the remaining mass of the two α subunits, primarily the connecting domains (CD).

The contiguity of the domain structure (Fig. 3B, top and side view 90°), along with the primary domain sequence (Fig. 4A), shows that the two β subunits occupy the lower half of the structure, distal from L1, reaching up and out as a contiguous mass. The intracellular TK domain of IR would then occupy the bottom portion of this structure with two IR fibronectin type III (FnIII) repeats in each receptor half being in the top portion of the crescent-shaped spiral of the β subunit at the same level as the L2 domain in the α subunit. One of the FnIII repeats, composed of residues from both the α and β subunit, is assigned to the upper left end of the crescent (side view, 0°) where it is contiguous with the CD portion of the α subunit (top view).. Fig. 4C and 4D (cf. Fig. 3B, 90°, top view, respectively) show the fitting of the crystal structure of the TK domain (green) of the β subunit and of the two FnIII repeats (blue/red) modelled as the canonical fibronectin type III structures (16).

The masses of the kinase domains are connected via a slender horizontal bridge (Fig. 3B, side view 90°) that was not observed in the x-ray structures of the TKs, but can be explained in terms of the reconstruction being in a transition between free IR and its ligand-activated form. In the two symmetrically fitted TK (Fig. 4C and 4D) crystal structures the catalytic loops are separated by 4 nm. This distance is just sufficient to permit the tyrosine triplet (Tyr1158, 1162 and 1163) in a fully extended flexible activation loop of one TK to reach the catalytic loop of the opposite TK as modelled from the x-ray coordinates (PDB 1IRp). The extension of the activation loops, equivalent in cross-section to four extended polypeptide chains, easily accounts for the linking density observed between the lower portions of the β subunits (Fig. 3B, 90°). This is an important difference from the x-ray structures of the inactive and activated TKs as discussed below.

The spatial relationship between the domains of the α and β subunits (e.g. side view, 90°) shows the location of the cell membrane lipid bilayer as the space below the α subunits and above the bridge linking the two assigned TK domains. Instead of a flat open region, this space in the 3D reconstruction forms a thick dome-like slab above the bridge with a thickness variation of 2.2 to 2.7 nm. This spacing is a change in shape from, and a decrease in the thickness expected for a membrane bilayer that would accommodate an

alpha-helical transmembrane domain (TM) of 23-26 hydrophobic amino acids. However, since the purified IR in the absence of its native membrane was fully active, the relative positions of the extracellular and intracellular domains must still represent a close to native arrangement.

5 The crossing L1-Cys-rich-L2 domains of the dimeric α subunits were presented (Fig. 4B and 4C). We determined the x-ray coordinates (5) (See Fig. 7). Nonetheless, using this structure, the localization of the gold cluster, and the known receptor-binding domain of insulin (8), we have tentatively fitted an NG-BI molecule into this region. The best fit is obtained with a molecule of insulin, partially on the two-fold symmetry axis of
10 the dimer, being in contact with the L1-Cys-rich domains of one α subunit and with the L2 domain of the other α subunit. A model involving both α subunits in the high-affinity binding of insulin has previously been proposed based on studies of insulin analogues binding to IR and IR/IGF-I R chimeras (8). Our 3D reconstruction shows this involvement. Although two molecules of insulin can be fitted to this configuration, two
15 molecules of Nanogold-labeled insulin were observed only rarely in the STEM images. The high-affinity binding of the first insulin molecule to the IR has induced a conformational change in the binding domain so that the second insulin molecule would bind only at low affinity. Likewise the binding of a second molecule of insulin could effect a conformational change that enhances the dissociation of the bound insulin. Thus
20 the curvilinear Scatchard plot and the negative cooperativity of insulin binding (9) can be explained on the basis of the 3D reconstruction. The reconstruction also explains why only low-affinity binding is obtained with purified $\alpha\beta$ monomer.

Superimposition of known crystal structures of smaller domains of the receptor on substructures of the 3D reconstruction has made it possible to deduce the spatial
25 relationship among the domains in the complex. The structure shows the division of the complex into the extracellular and the cytoplasmic segments along a plane, the cell membrane, on which the fibronectin type III repeats lie (16-18). These repeats appear pontoon-like to support the centrally located insulin-binding segment of the ectodomain.

Monomeric inactive receptor TKs such as EGFR are brought together by ligand binding and become activated as dimers resulting in TK autophosphorylation. In the intrinsically dimeric IR-family receptors, the distance between the two cytoplasmic β -subunit TKs within the dimer must be too great without ligand binding for the activation of the kinase. Hubbard *et al.* (4) suggested that insulin binding to IR decreased this distance by disengaging Tyr1162 from the catalytic loop to enable *trans* phosphorylation in the presence of ATP. In our reconstruction a good fit to the ligand-receptor complex is obtained when the two TK domains are oriented with their catalytic loops juxtaposed. In this orientation the extended flexible activation loop of each TK, which moves 30 Å between the inactive and activated states in the crystal structures (4), can just reach the catalytic loop of the opposing TK to be activated. These two loops can easily form the linking mass density between the TKs seen in the 3D reconstruction in the absence of ATP.

The 3D structure obtained from images of the HIR-complex containing only a single NG-BI, shows that one molecule of insulin is sufficient to bring the two $\alpha\beta$ monomers to an activating configuration. The dimeric receptor with a Ser323Leu mutation in the L2 domain of both α subunits showed a severe impairment in insulin binding, whereas a hybrid receptor with only one of the two α subunits mutated was found to bind insulin with high affinity and was fully active as a tyrosine kinase. Based on our 3D reconstruction, insulin bound to the L1 domain of the mutant α subunit and the wild-type L2 domain of the hybrid IR and the binding of only a single molecule of insulin is sufficient for TK activation.

Thus we have obtained the 3D quaternary structure of the IR-insulin complex formed in the absence of ATP. The structure was an intermediate between insulin-free IR and the fully activated, phosphorylated IR. The reconstruction is readily interpreted as such: as a receptor poised for activation by *trans*-phosphorylation. We determine the full extent of conformational changes induced by insulin binding. We reconstruct the initial state of free IR and the final activated state for comparison. The 3D reconstruction presented here provides concrete structural information towards the full understanding of transmembrane signal transmission in insulin action. Furthermore, the approach used in this study can be applied to obtain the quaternary structure of other membrane proteins or receptors that are

refractory to crystallization. The invention includes the methods for studying polypeptide structure described in this application.

Example 3 - Mechanics of Transmembrane Signalling of the Insulin Receptor

5 The binding of insulin to the extracellular domain of the insulin receptor (IR) begins an intracellular signal cascade that ends in numerous insulin-specific cellular responses. The binding event activates the intracellular tyrosine kinase (TK) domain of the receptor. How the signal is transmitted across the cell membrane has remained a mechanistic puzzle, since complete membrane receptors have been refractory to high resolution structural studies by
10 NMR spectroscopy or by crystallography. In an alternative approach we have used low-dose low-temperature dark field scanning transmission electron microscopy (STEM) to determine the three-dimensional quaternary structure of the entire isolated 480 kDa human insulin receptor bound to insulin¹. Recently the atomic co-ordinates of individual N-terminal domains of the extracellular region of a highly homologous receptor, the insulin-like growth factor type 1 receptor (IGF-1R) have become available, as have models of the
15 three individual fibronectin type III (Fn) domains of IR^{10,31}. We have modified these domain structures substituting the IR amino acid sequence and accommodating the covalent dimeric character of IR. The IR TK domain structures were available previously^{8,9}. All of these domains were fitted into the quaternary structure calculated from STEM micrographs. The
20 fit provides a detailed description of the insulin binding site of IR and of its interactions with insulin. Moreover, the entire 3D complex is a molecular machine with intrinsic linkages that provides a mechanistic model for transmembrane signal transduction by IR. Since IR is constitutively dimeric², the mechanism of IR signal transduction is of necessity different from that of many receptors activated by ligand-induced dimerization. Instead, the
25 binding of insulin changes the IR dimer from a configuration that inhibits TK activation to one that is openly permissive of TK transphosphorylation.

The structure and model explain observations on insulin binding, on disulphide modifications linking the two monomers and linking their constituent domains, the block to

We claim:

1. A method of identifying a compound that modulates insulin receptor activity, comprising producing a compound that interacts with all or part of the fitted quaternary structure of insulin receptor or a fragment or derivative thereof and which thereby modulates insulin receptor activity.
2. The method of claim 1, further comprising synthesizing the compound.
3. A method of identifying a compound that modulates insulin receptor activity, comprising comparing the structure of a compound for modulating insulin receptor activity to all or part of the fitted quaternary structure of insulin receptor or a fragment or derivative thereof to determine whether the compound is likely to modulate insulin receptor activity.
4. The method of claim 1 or 3, further comprising determining whether the compound modulates the activity of the insulin receptor or a fragment or a derivative thereof having insulin receptor activity in an *in vivo* or *in vitro* assay.
5. The method of claim 1 or 3, wherein the compound comprises an insulin receptor agonist or an IR antagonist.
6. The method of claim 1 or 3, wherein the fitted quaternary structure of insulin receptor comprises substantially the entire fitted quaternary structure of insulin receptor.
7. The method of claim 1 or 3, further comprising:
 - a) introducing into a computer program information defining a ligand binding site conformation including at least one residue from monomer A in Table I and at least one residue from monomer B in Table I, the ligand binding site defined by the approximate amino acid distances listed in Table I, wherein the program displays the quaternary structure thereof;
 - b) comparing the structural coordinates of the compound to the structural coordinates of the ligand binding site and determining whether the compound fits spatially

into the ligand binding site and is capable of changing insulin receptor from an inactive conformation to an active conformation or biasing insulin receptor toward an active conformation;

wherein the ability to change insulin receptor from an inactive conformation to an active conformation or bias insulin receptor toward an active conformation is predictive of the ability of the compound to agonize insulin receptor activity.

8. The method of claim 7, further comprising preparing the compound that fits spatially into the ligand binding site and determining whether the compound agonizes insulin receptor activity in an insulin receptor activity assay.

9. The method of claim 1 or 3, further comprising:

a) introducing into a computer program information defining a ligand binding site conformation including at least one residue from monomer A in Table I and at least one residue from monomer B in Table 1, the ligand binding site defined by the approximate amino acid coordinates listed in Table 1, wherein the program displays the quaternary structure thereof;

b) comparing the structural coordinates of the compound to the structural coordinates of the ligand binding site and determining whether the compound fits spatially into the ligand binding site and is capable of changing insulin receptor from an active conformation to an inactive conformation or biasing insulin receptor toward an inactive conformation;

wherein the ability to change insulin receptor from an active conformation to an inactive conformation or bias insulin receptor toward an inactive conformation is predictive of the ability of the compound to antagonize insulin receptor activity.

10. The method of claim 9, further comprising preparing the compound that fits spatially into the ligand binding site and determining whether the test compound antagonizes insulin receptor activity in an insulin receptor activity assay.

11. The method of claim 1 or 3, further comprising:

a) introducing into a computer program information defining a cam including at least one residue from the Cam-loop segment in Table 2 and at least one residue from the L1 surface in Table 2, wherein the program displays the quaternary structure thereof;

b) comparing the structural coordinates of the compound to the structural coordinates of the cam and determining whether the compound interacts with the cam and is capable of changing insulin receptor from an inactive conformation to an active conformation or biasing insulin receptor toward an active conformation;

wherein the ability to change insulin receptor from an inactive conformation to an active conformation is predictive of the ability of the compound to agonize insulin receptor activity.

12. The method of claim 11, further comprising preparing the compound that interacts with the cam and determining whether the test compound agonizes insulin receptor activity in an insulin receptor activity assay.

13. The method of claim 1 or 3, further comprising:

a) introducing into a computer program information defining a cam conformation including at least one residue from the Cam-loop segment in Table 2 and at least one residue from the L1 surface in Table 2, wherein the program displays the quaternary structure thereof;

b) comparing the structural coordinates of the compound to the structural coordinates of the cam and determining whether the compound interacts with the cam and is capable of changing insulin receptor from an active conformation to an inactive conformation;

wherein the ability to change insulin receptor from an active conformation to an inactive conformation or bias insulin receptor toward an inactive conformation is predictive of the ability of the compound to antagonize insulin receptor activity.

14. The method of claim 13, further comprising preparing the compound that interacts
5 with the cam and determining whether the test compound antagonizes insulin receptor activity in an insulin receptor activity assay.

15. The method of any of claims 1 or 3, wherein the insulin receptor is bound to insulin.

16. A computer medium having recorded thereon data of an insulin receptor, said data
10 sufficient to model all or part of the fitted quaternary structure of the receptor.

17. The computer medium of claim 16, wherein the data comprises structural coordinates of an IR receptor, the coordinates sufficient to model all or part of the quaternary structure of the receptor.

18. The computer medium of claim 16, wherein the quaternary structure of the
15 receptor comprises substantially all of the quaternary structure of the receptor.
